1. Some highly confidential documents need to be kept in a super secured vault.The vault has 5 steps of security check points without any human security personnel. Only an authorized person gets 5 different passwords to open and close 5 different security gates. Each password is affective to open and close the very same gate once. You have to enter 5 different authorized passwords to open 5 different gates. You have to keep track which password was used to open one gate, so that you can close the gate with the same password after finishing your job in the vault. You will finish your job in the vault and lock the series of gates using the correct sequence (which one you used to enter) of passwords. The passwords will be of string type. Which data structure would you choose to keep track of the sequence of passwords to access the vault? Write a pseudo-code of insertion and deletion function of that correct data structure.

2. In our national parliament, MPs arise hand if they want to say anything in point of order. Honorable speaker of national parliament decided that he want to automate this process. If an MP wants to say anything in point of order, then s/he must send a request to the speaker by a mobile app. When the speaker decides to give time for the point of order, an automatic system will call the name of the MP's. The system will maintain a sequence so that the MP who requested first will get the floor first. Now, your task is to identify and write the pseudocode of an appropriate data structure that can be used for saving the request of the MP's so that the automatic system can use that for calling the name of the MPs. Assume that every MP has an ID which is an integer number. You will save only this ID in your data structure.
