Homework Assignment - 2

1)

a) Write down the Pseudo-Code of Prim-Jarnik Algorithm.

b) There are seven small islands in a lake, and the state wants to build bridges to connect them so that each island can be reached from any other one via one or more bridges. The cost of constructing a bridge is proportional to its length. The distances between pairs of islands are given in the following graph.

c) Find which bridges to build so that total construction cost is minimum, use appropriate algorithm where 'a' is the start node. Show your simulated work, and what is the minimum cost.
